	The Number Formatting	148

CHAPTER 1 - GROUPING IN TABLES

1.1 Grouping Basics

Applying *grouping* to a table allows you to organise the data into discrete sections. This can make it easier to display and print the data.

In a grouped table the detail rows appear in neatly organised sections. In this example we've grouped films by the country in which they were made.

Australia							
Title	Release Date	Run Time					
Crocodile Dundee II	25/05/1988	112					
Crocodile Dundee	26/09/1986	98					
Happy Feet	17/11/2006	108					
Mad Max	12/04/1979	93

You can even create fancy collapsing and expanding groups to add a little interactivity to your reports.

Đ	Australia							
P	Brazil							
7 💭 e	Release Date	Run Time						
City of God	30/08/2002	130						
	Total	130						
Ŧ	Canada							

You can also apply groups to columns in a table but this chapter focusses on grouping rows. The **Matrix** report item is a **Table** with pre-defined row and column groups and you'll learn about this in a later chapter.

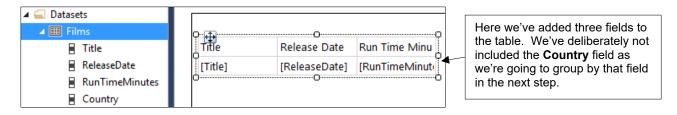

1.2 Grouping Rows in a Table

There are several steps involved in creating a grouped table, as detailed in this section.

Step 1 – Build a Basic Table

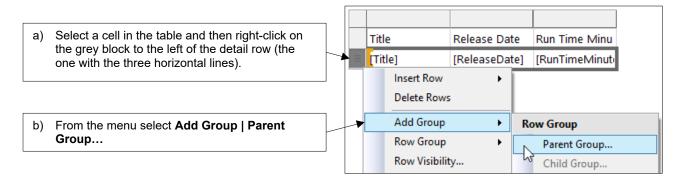

Start by building a basic table containing the fields you want to see for each detail row.

Step 2 – Apply Grouping to the Detail Row

You can choose to apply grouping to the detail row in a table using one of several techniques:

Right-click on the detail row in the table.

• Right-click on the detail row in the **Grouping Pane**.

a) Right-click the (Details) item in the Row Groups	E Row Groups					
area of the Grouping Pane .	≡ (Details)					
	Add Group Parent Group					
b) Select Add Group Parent Group	Add Total S Child Group					

• Click and drag a field from the **Report Data** window to the **Grouping Pane**.

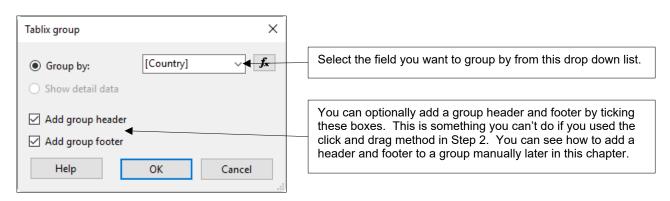

▲	Row Groups	
 Films Title ReleaseDate RunTimeMinutes Country 	= (Details) ↓▼	Clic colu in th imp (De

Click and drag the relevant field (here we're using the **Country** column) from the **Report Data** window onto the **(Details)** item in the **Grouping Pane**. A blue horizontal line will appear – it's important to release the mouse when the line sits above the **(Details)** item.

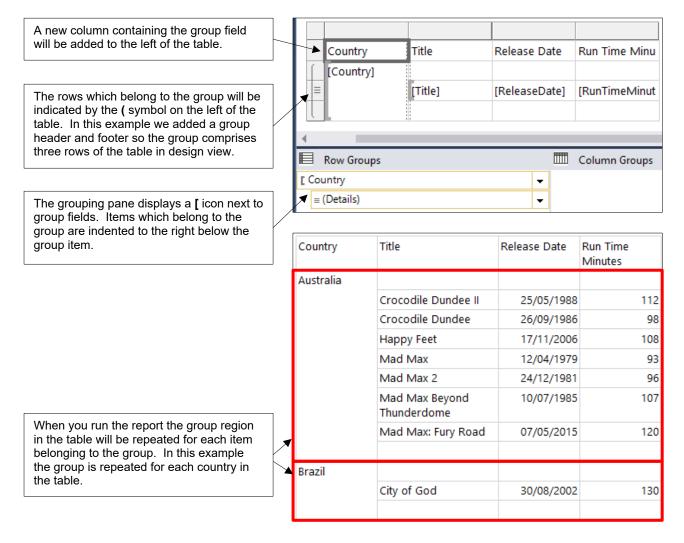

Step 3 – Choose Which Field to Group By

If you used the right-click menu to add a group in Step 2 you'll need to complete a dialog box to specify which field you're grouping by.

The End Result

When you've finished applying grouping to the table it should look somewhat different:

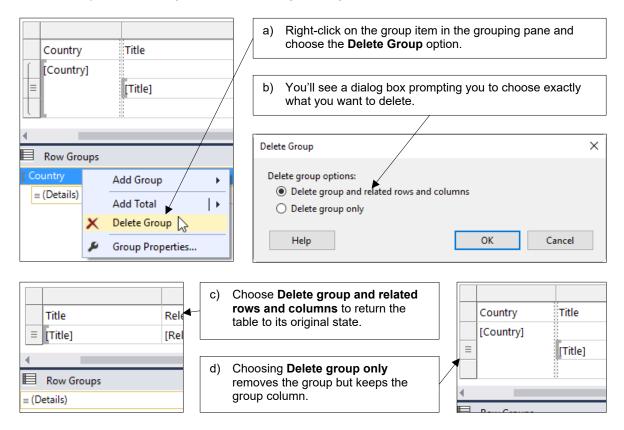

1.3 Removing Groups

You can delete a group along with its associated rows to return your table to its original state.

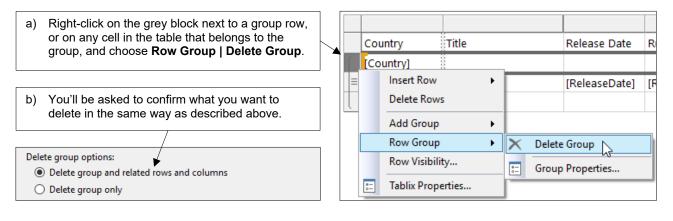

Deleting Groups in the Grouping Pane

The easiest way to delete a group is from the grouping pane.

Deleting Groups in a Table

You can also delete a group by right-clicking inside a table.

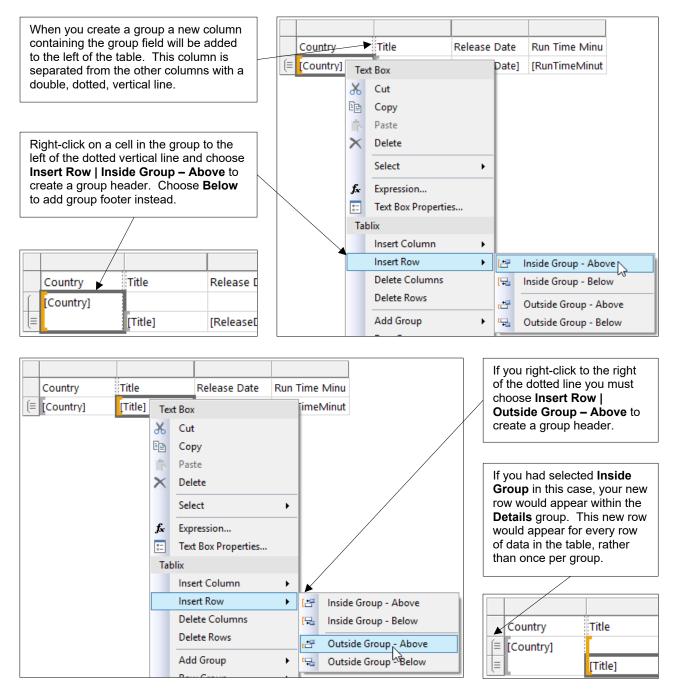

1.4 Formatting a Grouped Table

The default layout and formatting of a grouped table isn't particularly attractive. You can do several things to alter the default appearance, as explained in this section.

Adding Group Headers and Footers

If you used the click and drag method to create a group, or you just forgot to tick the boxes on the dialog box when you created the group, you can add a header and footer to a group manually.

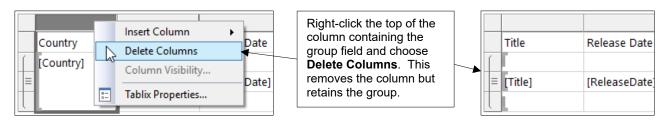

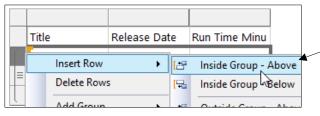

Rearranging Group Titles

By default the group title appears in a new column to the left of the grouped rows. You may find it looks better to move this title into a row which sits above the group. The steps to do this are:

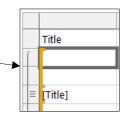

1) Delete the column which contains the group title:

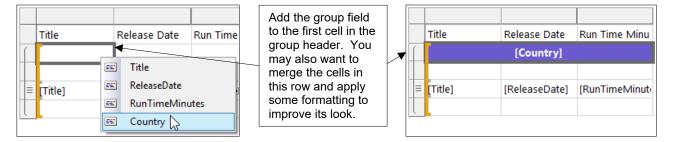

2) Insert an extra row for the group header:

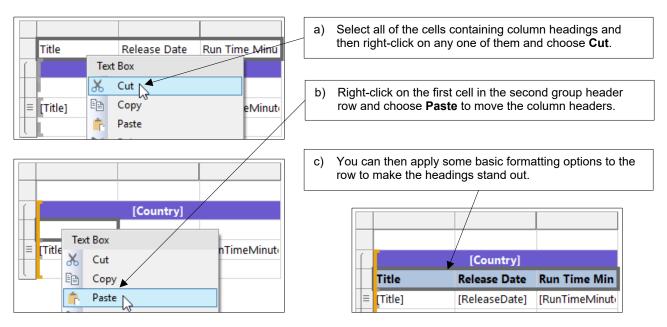

Right-click to the left of the group header row and choose **Insert Row | Inside Group – Above**. This will leave you with two rows in the group header section of the table.

3) Assign a field to the group header cell:

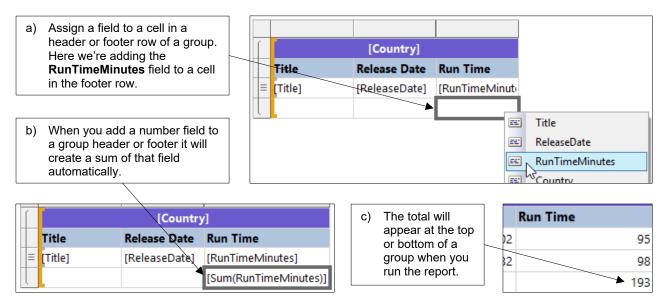

4) Move the column headings.

Adding Group Totals

You can add aggregated values to either a header or footer of a group to show totals, averages, etc:

You can change the function applied to the field to create different aggregates.

to make the results	s readable!			104.857142857143

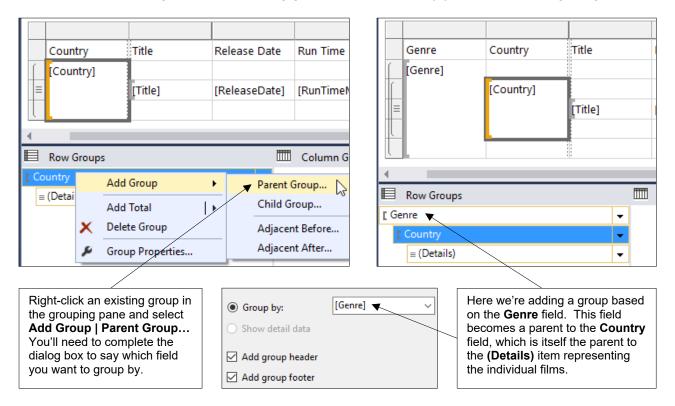

1.5 Multiple Groups

Once you've created one group, adding more is simple!

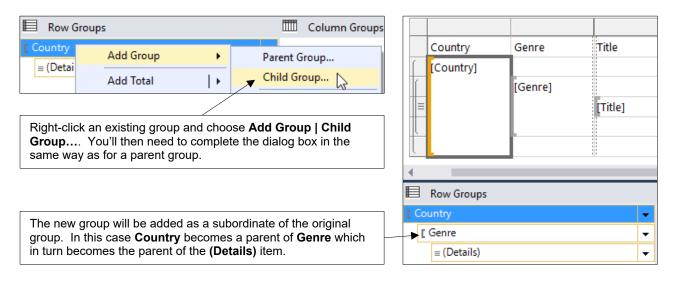

Adding a New Parent Group

You can add a parent group to an existing group in the same way you added the original group:

Adding a Child Group

You can add a *child group* to an existing group, as shown in the diagram below:

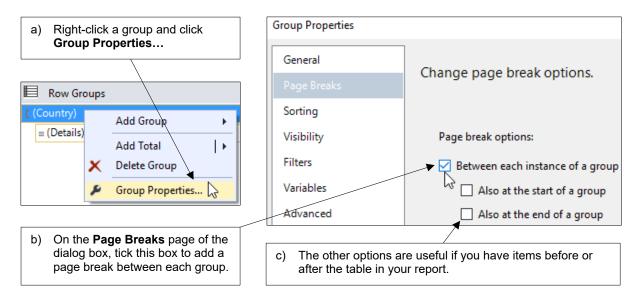

1.6 Page Breaks

You may find it useful to have each group start on a new page, rather than simply following on immediately after the previous group in the table.

Inserting Page Breaks between Groups

You can add a page break between each group using the Group Properties dialog box.

You should notice a difference when you run the report:

I≪ 4 1 of 2? ▶ ▶ ♦	🛞 🚱 🌲 🛙	10 🔍 🔍

1.7 Collapsible Groups

Creating collapsible groups allows you to show and hide the detail rows in a group when the report is running.

Step 1 - Hiding Detail Rows

The first step in creating a collapsible group is to ensure that the detail rows and any associated column headers and footers are hidden when the report loads.

Select an item in the Grouping Pane that you want to hide and then change its **Hidden** property to **True** in the **Properties** window. For this example we would hide the **(Details)** item and the **(Static)** item immediately above and below it. You must do this separately for each item that you want to hide.

When you run the report you should only be able to see the items in the table that you didn't hide.

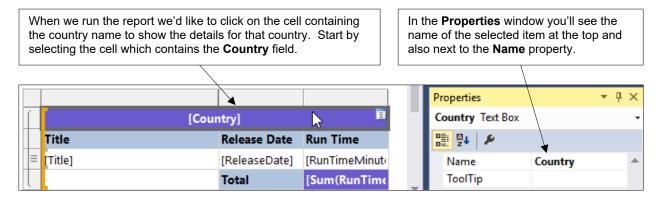

📐 Design	hereview			
4 4 1	of 1 🕨 🕅 🗧 🛞 🕲 🖨 🗐 江 🔍 -			
	Australia			
Brazil				
Canada				
	China			

All of the detail rows and the column headers and group footer rows have been hidden.

Step 2 - Setting Toggle Items

The *toggle item* is the report item that you will click on to show and hide the detail rows in each group. The first thing you need to do is find out the name of this item.

Having established the name of the item you'd like to click on, you can set this object to be a toggle item using the grouping pane and **Properties** window.

Row Groups		Column Groups	-		KeepTogether	False	
[(Country)	-	(Static)			KeepWithGroup	After	
(Static)		(Static)			RepeatOnNewPag	False	
(Static)		(Static)			Visibility		
≡ (Details)	.				Hidden	True	
(Static)				₹	Toggleltem	Country	\sim
(otatic)				т.			2

Select an item in the grouping pane whose visibility you want to control. You can then assign an item to toggle its visibility using the **ToggleItem** property in the **Properties** window. You need to do this separately for each item whose visibility you want to control. In our example we need to do this for three items.

When you run the report you should find that you can show and hide items in a group by clicking the + and – symbols which appear in the text box containing the country name.

Click a + symbol to expand a collapsed group.		Australia Brazil

CHAPTER 2 - EXPRESSIONS

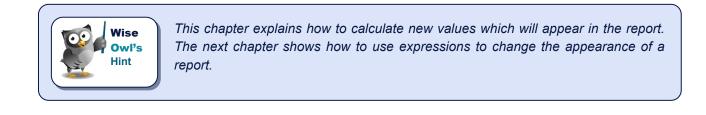

2.1 Overview of Expressions

Expressions are calculations that are evaluated when you run a report to determine some aspect of the report. They crop up almost everywhere in SSRS, as this chapter will show you!

Choosing to Create an Expression

You can add an expression to calculate a value in a variety of places in a report.

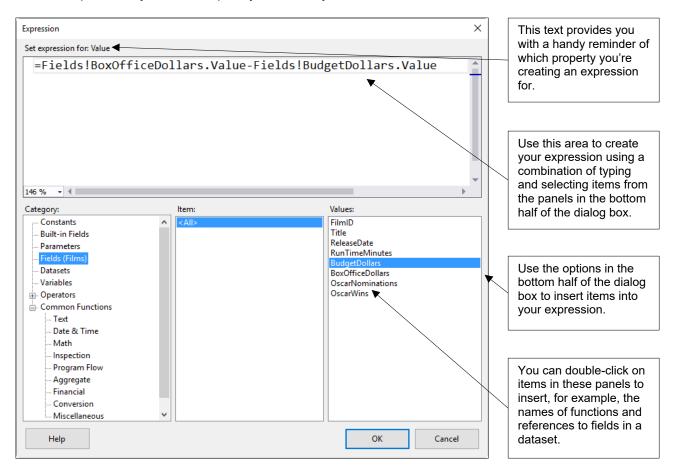

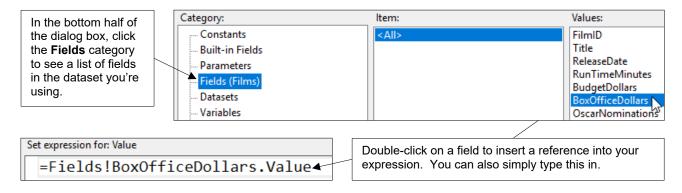

The Expression Builder Dialog Box

When you choose to create an expression you'll be presented with the *Expression Builder* dialog box. This provides you with help as you create your calculation.

Referring to Dataset Fields

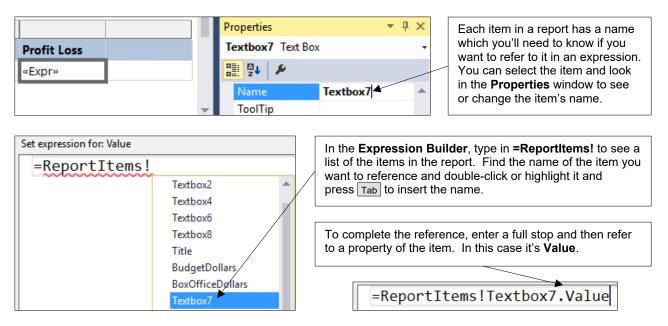

Many of your expressions will refer to the value of fields in a dataset. You can insert references to fields easily using the **Expression Builder**.

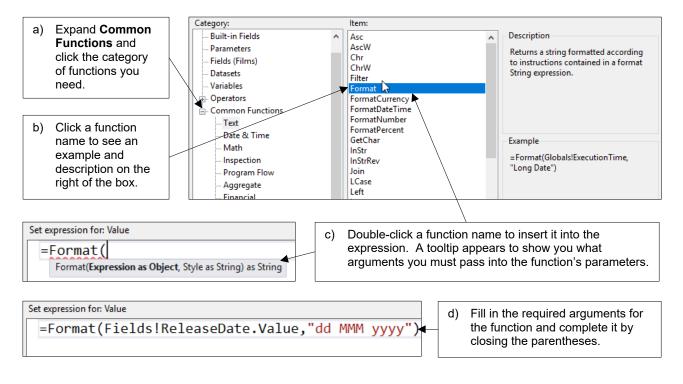

Referring to Report Items

You'll sometimes need to refer to an item in the report, for example, to return the value of a textbox. The **Expression Builder** doesn't list report items so you'll need to do some typing.

Inserting Functions

You can use a variety of functions in your expressions. Rather than trying to remember the names of all the available functions, you can use the **Expression Builder** to insert them.

2.2 Ad-Hoc Table Columns

You can use *ad-hoc* expressions to create new calculated columns in a table. The table in the diagram below has two columns whose values are calculated using ad-hoc expressions.

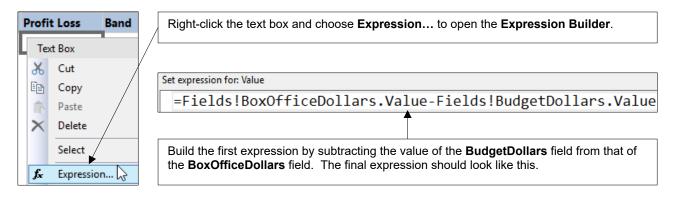

Title	Budget	Box Office	Profit Loss	Band
Jurassic Park	6300000	1029939903	966939903	Profit
Spider-Man	14000000	821708551	681708551	Profit
King Kong	20700000	550500000	343500000	Profit
Superman Returns	20400000	391081192	187081192	Profit
Titanic	20000000	2186772302	1986772302	Profit
Evan Almighty	175000000	173418781	-1581219	Loss

The **Profit Loss** column is calculated by subtracting the value of the **Budget** field from that of the **Box Office** field.

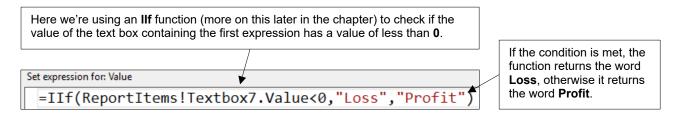

The **Band** column is calculated using an **IIf** function to determine if the value of the **Profit Loss** item is less than **0**.

Creating an Ad-Hoc Column Expression

You can calculate the value of a text box in a table by adding an expression directly to it.

Once you've created the first expression you can create a new column which refers to it. You'll need to know the name of the text box which contains the first expression to do this.

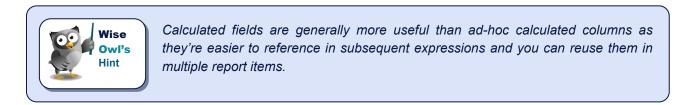

The examples on this page would be more useful as calculated fields, as described in the next section. Ad-hoc column expressions are still useful however, as some functions in SSRS can't be used in a calculated field.

2.3 Calculated Fields

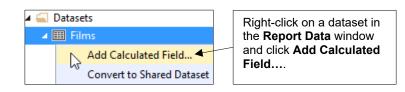

A *calculated field* is an expression which creates a new field in a dataset. You can use calculated fields in the same way as built-in fields to, for instance, sort and filter items in the dataset.

Adding a Calculated Field to a Dataset

Adding a calculated field takes a little more effort than adding an ad-hoc column expression. Here are the steps you'll need to follow:

1) Choose to add a calculated field to a dataset.

2) Provide a name for the field and launch the **Expression Builder**.

Field Name	Field Source		T C U C U
Title	Title	a)	Type a name for the field without using spaces.
BudgetDollars	BudgetDollars		
BoxOfficeDollars	BoxOfficeDollars	b)	Click here to open the Expression Builder dialog
ProfitLoss			box.

3) Create the expression.

Expression		
Set expression for: Value =Fields!BoxOfficeDollars.Value-Fields!BudgetDollars.Value	r	Build an expression in the usual way.

When you've clicked OK a couple of times in the dataset field list.	 Datasets Films 		
	Calculated fields are listed in the dataset in the same way as other fields.		 Title BudgetDollars BoxOfficeDollars ProfitLoss

Using a Calculated Field

Once you've created a calculated field you can use it in the same way as any other field. For example, you can:

• Add the field to a report item such as a table.

Box Office			
[BoxOfficeDollars]			Here we're using the field
] Title	selector in a cell in a table
		BudgetDollars	to choose the ProfitLoss
	E4.	BoxOfficeDollars	calculated field.
		ProfitLoss	
		-2	

• Apply sorting to a report item.

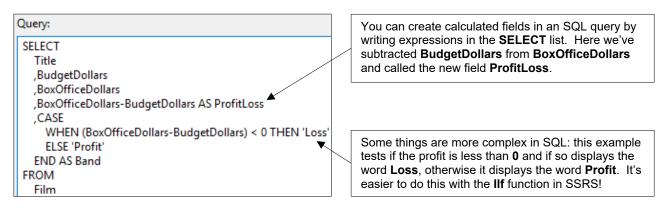

Filters Sorting	Add Delete 😔 🚸	You can select a calculated field
	Column Order	from the Sort by drop down list.
	Sort by [ProfitLoss] < \sqrt{\vec{f_x}} A to Z \sqrt{\vec{f_x}}	

Apply filtering to a dataset or report item.

Filters Sorting	Include rows where the following conditions are true. Add Delete	You must choose the correct data type when using a calculated field in
	Expression [ProfitLoss] V 🖌 Integer 4 V	a filter. This field calculates a whole
	Operator > ~	number so we use the Integer type.
	Value 0 f x	

Adding Calculated Fields to a Query

If you know how to write SQL you may prefer to add calculated columns to a dataset's query.

2.4 Working with Numbers

Some of the simplest expressions you'll create will involve numbers. This page describes a few of the basic things you can do to manipulate numeric data in SSRS.

Basic Arithmetic

You can perform arithmetic on numbers by placing an *operator* between them. The table below lists the arithmetic operators in SSRS:

Operator	What it does	Example	Result
+	Adds two values together.	3 + 2	5
-	Subtracts one number from another	3 – 2	1
*	Multiplies two numbers together.	3 * 2	6
/	Divides one number by another and returns a decimal number.	3 / 2	1.5
١	Divides one number by another and returns a whole number.	3\2	1
^	Raises one number to the power of another.	2 ^ 3	8
Mod	Returns the remainder of dividing one number by another.	3 Mod 2	1

Numeric Functions

You can use several numeric functions to manipulate numbers in interesting ways. You can see a summary of some useful numeric functions in the table below:

Function	What it returns	Example	Answer
Abs(number)	The absolute value of a number.	Abs(-5)	5
Ceiling(number)	The next largest whole number.	Ceiling(3.147)	4
Floor(number)	The next smallest whole number.	Floor(3.147)	3
Int(<i>number</i>)	ine integer person et a namber i et		9
	negative numbers it returns the next lowest whole number.	Int(-9.81)	-10
Round(<i>number</i> ,	A number rounded to a whole number or	Round(3.147)	3
[number of decimal places])	an optional number of decimal places.	Round(3.147, 2)	3.15
Sqrt(number)	The square root of a number.	Sqrt(16)	4

You'll find all of the functions shown above, along with many others, in the **Math** category of functions in the Expression Builder.

2.5 Conditional Functions

Conditional functions are those which return a different answer depending on the result of evaluating a logical test.

The IIf Function

The *IIf* function allows you to test a condition and provide a different answer depending on whether or not it has been met. The basic syntax of the **IIf** function is:

=IIf(Condition To Test, Answer If True, Answer If False)

The slightly harsh example below tests whether a film has won any Oscars and, if so, describes it as a **Winner**, otherwise it calls the film a **Loser**.

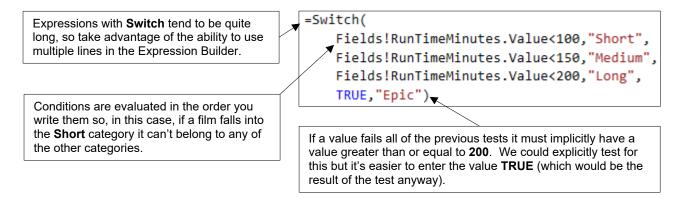

Set expression for: Value		Title	Oscars	Success
=IIf(Fields!OscarWins.Value>=1,"Winner","Loser")		Jurassic Park	3	Winner
↑		Spider-Man	0	Loser
The results of this expression are shown on the right. As we suspected:		King Kong	3	Winner
wearing your underpants outside your trousers does make you a loser.		Superman Returns	0	Loser

The Switch Function

The *Switch* function is helpful for testing multiple conditions in the same expression. The basic syntax of the **Switch** function is:

```
=Switch(Condition1, Answer1[, Condition n, Answer n])
```

The example below categorises films based on their length in minutes.

Comparison Operators

A *comparison operator* is the symbol that you place between the two values you're testing. The table below describes the comparison operators you can use in SSRS.

Operator	Description	Operator	Description
=	ls equal to	<>	Is not equal to
>	Is greater than	<	Is less than
>=	Is greater than or equal to	<=	Is less than or equal to

Logical Operators

A *logical operator* affects the way your conditional tests are evaluated. There are three main logical operators you're likely to encounter in SSRS:

Operator	Description	Example
AND	Combines two logical tests and returns True if both conditions are met.	=IIf(Fields!Profit.Value>0 AND Fields!OscarWins.Value>0, "Success", "Failure")
OR	Combines two logical tests and returns True if either condition is met.	=IIf(Fields!Profit.Value<0 OR Fields!OscarWins.Value=0, "Failure", "Success")
NOT	Returns the opposite of a logical value.	=IIf(NOT(Fields!Profit.Value>0 OR Fields!OscarWins.Value>0), "Disaster","Success")

2.6 Working with Text

You can manipulate text, or *strings*, in a variety of ways in SSRS. Bear in mind that most string operations in SSRS are case-sensitive.

Concatenating Text

Joining strings together, or *concatenating* them, is one of the more common operations you'll perform with strings.

Set expression for: Value	Use the &
=Fields!FirstName.Value & " " & Fields!FamilyName.Value	pieces of te

Use the **&** symbol to join two pieces of text together.

Text Functions

The table below describes some of the useful text functions you'll find in SSRS:

Function	What it returns	Example	Answer
<pre>InStr(string1, string2, [compare])</pre>	The position of the specified character in the string.	=InStr("Wise Owl", "w")	7
LCase(<i>string</i>)	The lower case version of the string.	=LCase("Wise Owl")	wise owl
Left(string, length)	The specified number of characters from the left of the string.	=Left("Wise Owl", 4)	Wise
Len(<i>string</i>)	The number of characters in the string.	=Len("Wise Owl")	8
LTrim(<i>string</i>)	The string without any leading spaces.	=LTrim(" Wise Owl")	Wise Owl
<pre>Mid(string, start, [length])</pre>	The specified number of characters from a given starting position in the string.	=Mid("Wise Owl", 6, 3)	Owl
<pre>Replace(string, find, replace, [start], [count], [compare])</pre>	The string with the specified characters replaced by a new string.	=Replace("Wise Owl", "w", "O", 1, -1, vbTextCompare)	Oise OOI
Right(string, length)	The specified number of characters from the right of the string.	=Right("Wise Owl", 3)	Owl
RTrim(<i>string</i>)	The string without any trailing spaces.	=RTrim("Wise Owl ")	Wise Owl
Trim(<i>string</i>)	A string without leading or trailing spaces.	=Trim(" Wise Owl ")	Wise Owl
UCase(string)	The upper case version of the string.	=UCase("Wise Owl")	WISE OWL

For functions with a **Compare** parameter, you can use **vbBinaryCompare** for case-sensitive searches and **vbTextCompare** to make the search case-insensitive.

2.7 Working with Dates

You can manipulate dates in a variety of ways in SSRS.

Returning the Current Date

Many date expressions rely on knowing what the current date is. The table below describes a few ways to get the current date.

Expression	What it does
=Today()	Returns the current date which is recalculated each time a new page is loaded.
=Now()	Gives the current date and time. This recalculates each time a new page loads.
=Globals!ExecutionTime	Returns the current date and time and is calculated when the report first loads.

Date Functions

You can use a variety of functions to work with dates in your report. The examples in the table below assume that today's date is Monday 19th June 2017.

Function	What it returns	Example	Answer
DateAdd(interval, number, date)	A date to which a specified time interval has been added.	=DateAdd("d", 30, Today())	6/19/2017
DateDiff(interval, date1, date2)	The number of specified intervals between two dates.	=DateDiff("d", Today(), #12/25/2017#)	189
DateSerial(year, month, day)	A complete date from the three separate values.	=DateSerial(2017, 7, 16)	7/16/2017
DateValue(<i>date</i>)	A date value based on the provided date, which is usually a string.	=DateValue(``18 July 2017")	7/18/2017
Day(<i>date</i>)	The day of the month of the date.	=Day(Today())	19
Month(date)	The month number of the date.	=Month(Today())	7
MonthName(<i>number</i>)	The name of the numbered month.	=MonthName(6)	June
Weekday(<i>date,</i> [firstdayofweek])	The number of the day of the week.	=Weekday(Today(), vbSunday)	2
WeekdayName(number, [abbreviate], [firstdayofweek])	The name of the numbered weekday.	=WeekdayName(2, False, vbSunday)	Monday
Year(date)	The year of the provided date.	=Year(Today())	2017

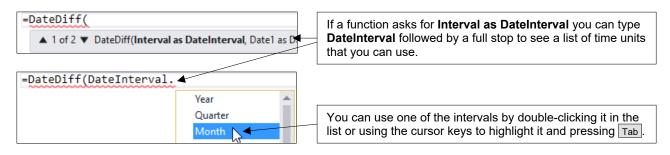

Intervals for Date Functions

Several of the date functions have an **Interval** parameter. The table below lists the string values you can pass as arguments to this parameter:

Interval	Description	Interval	Description
"УУУУУ"	Year	``w	Weekday
"q"	Quarter	"ww"	Week
``m″	Month	"h″	Hour
"y"	Day of year	"n″	Minute
"d″	Day of month	"s"	Second

Rather than passing a string to the **Interval** parameter, you can use one of the **DateInterval** constants.

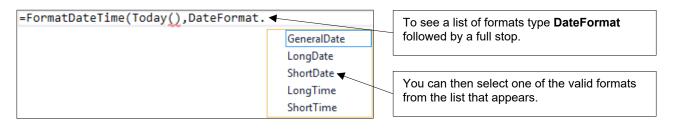

Formatting Dates

You can use functions to calculate a formatted version of your date values. There are two functions that can help you with this, as shown in the table below:

Function	Example	Result
<pre>Format(value, [format], [firstdayofweek], [firstweekofyear])</pre>	Format(Today(), "dddd, d MMMM yyyy")	Monday, 19 June 2017
<pre>FormatDateTime(date, [namedformat])</pre>	FormatDateTime(Today(), DateFormat.LongDate)	19 June 2017

There are several named formats that you can use with the FormatDateTime function:

2.8 Aggregating Data

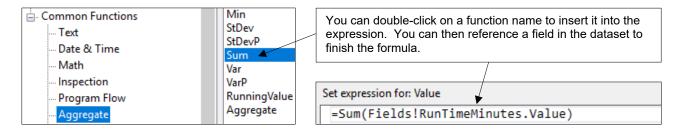

An *aggregate* function is one which usually operates on several rows of data rather than just one. You'll commonly find these functions used in table group footers, matrices and charts.

Aggregate Functions

You can see a list of some common aggregate functions in the table below:

Function	What it returns	Example		
Sum(Field)	The total of a numeric field.	=Sum(Fields!OscarWins.Value)		
Avg(Field)	The average of a numeric field.	=Avg(Fields!RunTimeMinutes.Value)		
Min(Field)	The lowest value of a field.	=Min(Fields!BudgetDollars.Value)		
Max(Field)	The highest value of a field.	=Max(Fields!BoxOfficeDollars.Value)		
Count(Field)	The number of non-null values in a field.	=Count(Fields!FilmID.Value)		

You'll find these functions, along with several others, in the **Aggregate** category of the **Common Functions** list in the **Expression Builder**.

Adding Aggregates the Quick Way

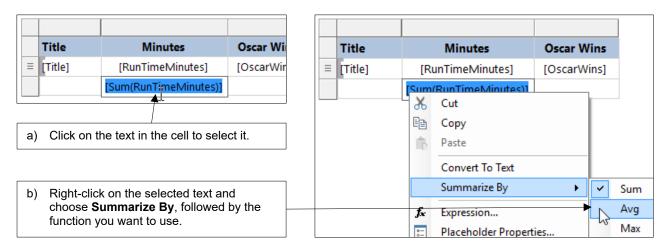

You can quickly add an aggregate function to a tablix report item by adding a field to cell which doesn't belong to a **Detail** row.

This table has a header and footer row and]		Director	Title	Minutes	Oscar Wins
contains a single group which also has a header and footer.		Ĺ	[Director]			
				[Title]	[RunTimeMinutes]	[OscarWins]
You can add an aggregate to a non-detail						
textbox by selecting a field from the field selector tool.						
						j Rummerminutes
Here we're choosing the RunTimeMinutes			Director	Title	Minutes	Oscar Wins
field in the footer of the group in the table.		Ĺ	[Director]			
		≡		[Title]	[RunTimeMinutes	[OscarWins]
This automatically adds a Sum function to]	l			[Sum(RunTimeMinut	tes)]
the footer of the group and of the table.			Total		[Sum(RunTimeMinut	tes)]

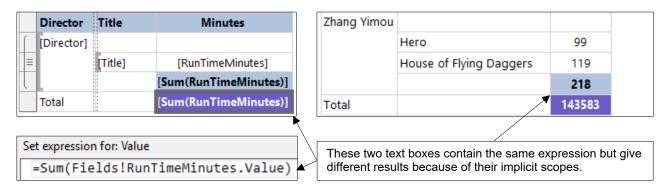

Changing the Aggregate Function

When you add an aggregate using the quick technique shown on the previous page, SSRS automatically applies the **Sum** function if you choose a numeric field. You can easily change this:

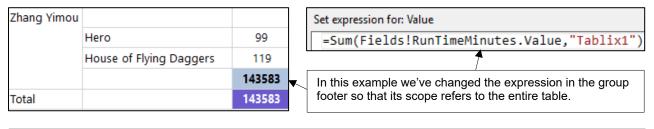

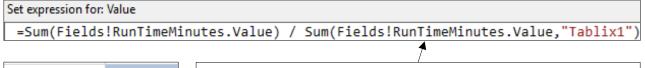

Specifying the Scope

The range of rows that an aggregate function operates on is referred to as the *scope*. The scope is applied automatically based on where the aggregate function is placed.

You can alter the scope by passing the name of a data region to an aggregate function. A data region name can be the name of a dataset, tablix report item or group.

% ▼ + 83

Here we've divided the total **RunTimeMinutes** for the group by the total for the table to calculate the proportion of the total run time made up by each director.

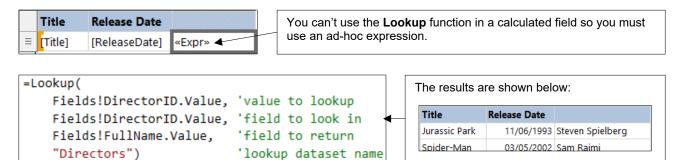

2.9 Lookup Functions

SSRS has two *lookup* functions which allow you to match rows in different datasets. This is useful when the datasets use different data sources and couldn't be joined in a single dataset.

🔺 🚄 Datasets	Title	ReleaseDate	DirectorID	DirectorID	FullName
🔺 🎹 Films	Raiders of the Lost Ark	1981-06-12 00:00:00.000	4	4	Steven Spielberg
Title	Star Wars: Episode IV: A New Hope	1977-05-25 00:00:00.000	7	5	Joel Coen
ReleaseDate	E.T.: The Extra-Terrestrial	1982-06-11 00:00:00.000	4	6	Ethan Coen
DirectorID	Fargo	1996-03-08 00:00:00.000	5	7	George Lucas
▲ I Directors				/	▼
DirectorID	The examples on this page use two separate datasets. The Films dataset contains the ID				
E FullName	number of each film's director. The name of the director is held in the Directors dataset.				

The Lookup Function

You can use the **Lookup** function to return a single match for the item you're looking up. In the example below we're attempting to return the name of the single director for each film.

The LookupSet Function

The **LookupSet** function is very similar to the **Lookup** function except that it returns multiple values. In the example below we're returning all of the films made by each director.

Full Name		The second column has an ad-hoc expression t		
Adam McKay	Talladega Nights: The Ballad of Ricky Bobby Anchorman: The Legend of Ron Burgundy	return the list of films.		
Adrian Lyne	Indecent Proposal Fatal Attraction Flashdance	We use the Join function to concatenate the film names returned into a single string.		
Akira Kurosawa	Seven Samurai Kagemusha Ran Rashomon Ikiru Throne of Blood The Hidden Fortress Yojimbo Sanjuro	=Join(LookupSet(Fields!DirectorID.Value, Fields!DirectorID.Value, Fields!Title.Value, "Films"), vbNewLine)		

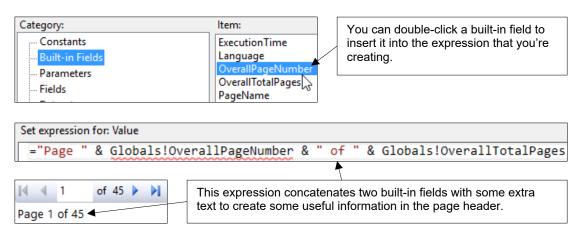

2.10 Built-In Fields

Reporting Services provides you with a set of global values referred to as *built-in* fields. You can use these to create expressions in your reports.

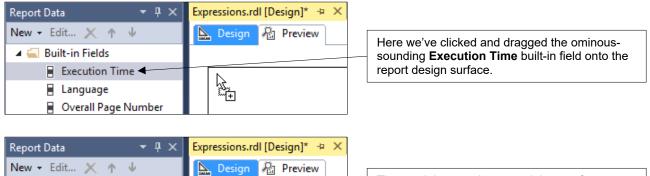

Built-In Fields in the Expression Builder

You can find a category containing the built-in fields in the **Expression Builder**.

Built-In Fields in the Report Data Window

You can drag built-in fields from the **Report Data** window in much the same way as dragging dataset fields.

Q & Execution Tim Q

×'n

The result is a text box containing a reference to the built-in field. You can edit this expression in the **Expression Builder** if you want to modify it.

🔺 🚄 Built-in Fields

Execution Time

Overall Page Number

Language

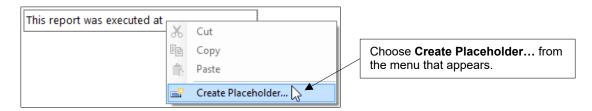

2.11 Placeholders

As an alternative to concatenating long, complex expressions, you can use a *placeholder* to make life easier.

Creating a Placeholder

You can insert a placeholder into a textbox alongside any other text that you want to display. To do this:

1) Right-click inside the text box at the position you'd like to create your placeholder.

2) Enter a label which describes the placeholder and then use the button shown below to open the **Expression Builder**.

Placeholder Properties		You can format a
General	Change label, value, and markup option <u>s</u> .	placeholder using this dialog box.
Number	change label, value, and markup options	
Alignment	Label:	
Font	TimeOfDay	Click here to open
Action	Value:	the Expression
	✓ Image: Section 2018 (1998)	Builder dialog.

3) Create an expression to calculate the value of the placeholder.

4) Click OK twice to insert the placeholder into the text box.

This report was executed at [TimeOfDay]	The placeholder sits alongside the normal text.

When your report runs, the placeholder will be calculated and display the result.

This report was executed at 11:30:32

We've applied some formatting to the placeholder.

What we do!
